CLOUDLESS.

The two machines to start with

Both are 128 GB unified-memory desktop appliances that run large models locally, and both begin as **retail units you configure and resell** — so neither needs funding to launch. Pick by one axis: **CUDA or not.**

START HERE · FASTEST TO REVENUE

Cloudless Spark

NVIDIA GB10 Grace-Blackwell · DGX Spark

Memory	128 GB unified LPDDR5X
Software	Full CUDA — catalog runs natively
Architecture	ARM64 (Grace CPU)
Storage	1–2 TB Gen4 NVMe
Retail base	~$3,500–4,000
Porting cost	≈ zero
Best for	Developers · max compatibility

Why first: it's CUDA, so vLLM / ComfyUI / your whole catalog run with no porting work. Buyable today as DGX Spark and OEM clones (Dell, ASUS, Gigabyte, Lenovo, MSI).

THEN THIS · VALUE & OWN-BRAND PATH

Cloudless Mini

AMD Ryzen AI Max+ 395 · Strix Halo

Memory	128 GB unified LPDDR5X-8000
Software	x86 Linux — ROCm / Vulkan / llama.cpp
Architecture	x86-64 (16× Zen 5)
Storage	1–2 TB Gen4 NVMe
Retail base	~$1,800–2,000
Porting cost	High (validate off-CUDA)
Best for	Value buyers · the own-brand future

Why next: half the price and the only path to building your own unit later (Sixunited is AMD's authorized Strix Halo ODM) — at the cost of porting the catalog off CUDA.

The one difference that decides everything

Spark = no porting, higher price, reseller forever.
CUDA means your software just works. But NVIDIA gates GB10 silicon to its OEMs, so you stay an integrator — you can't build your own.

Mini = porting work, lower price, can manufacture later.
x86 keeps the Linux world working but isn't native CUDA. The upside: a real path to your own branded hardware down the line.

How to start with zero funding: sell build-to-order — the customer pays first, you buy the retail unit with their money, flash CloudlessOS, tune and test it, then drop-ship. No inventory, cash-positive per order. Begin with **Spark** for revenue now; add **Mini** as the “someday we build our own” track. Let the first 10–20 orders tell you which the market wants.
